Reflections

1. Did your estimations reflect the actual effort?

Yes, I believe that the estimations were close to reality. The story points for such significant tasks as Calculation of the borrower's credit risk and Preparation of the repayment schedule were 8, while the ones for smaller and easier tasks was 3 or 5. When the sprint was done, I could see

that the estimations were justified by the actual effort. Story points should be used to compare the amount of work and complexity rather than actual hours.

2. Was your backlog well-prioritized?

Yes, it was. The most critical functions in the system were given the highest priority. The ability to view pending loans has Medium priority since it is not critical but is still a helpful feature. Moreover, the lab recommends prioritizing features based on their impact on the user.

3. How did your simulated sprint aligned to your plan?

The simulated sprint aligned to my plan since all the main tasks were completed. Firstly, the most complex and critical stories were taken from the backlog to the sprint. Then, in the next two iterations, the stories were moved from To Do to In Progress to Done. Thus, everything was well-planned, and all important features were taken to the current sprint. The lab actually recommends simulating the transition of the stories between the three states.

4. What did you learn about your team's capacity from the burndown chart?

The burndown chart allowed me to see how much work the team did during the sprint. Since everything was completed, I could see that the capacity of the team was well

estimated. Burndown charts are helpful in comparing the actual progress with the initial plan. That way, it is easier to see if the team did enough work during the sprint. Jira allows one to visualize this information to have a better perception of how much work is left. show work remaining and help judge whether the team is likely to finish within the sprint.
